

GO enrichment evaporates under proper panel background

Top-50 conserved genes from a panel

Whole-genome background:
730 enriched terms
(*'cell junction'* $p=5e-14$)

Shared-panel background:
0 enriched terms

Brain panels were already designed around neural/junction markers.
Running enrichment against whole-genome bg is circular.
Proper test uses the shared panel as the bg.

PiMorph's top-50 is NOT statistically distinguishable from the rest of the shared panel under the correct background.
